

Regime transitions associated with predictability of severe events

Laura Ferranti

L. Magnusson, F. Vitart, D. Richardson, M. Rodwell

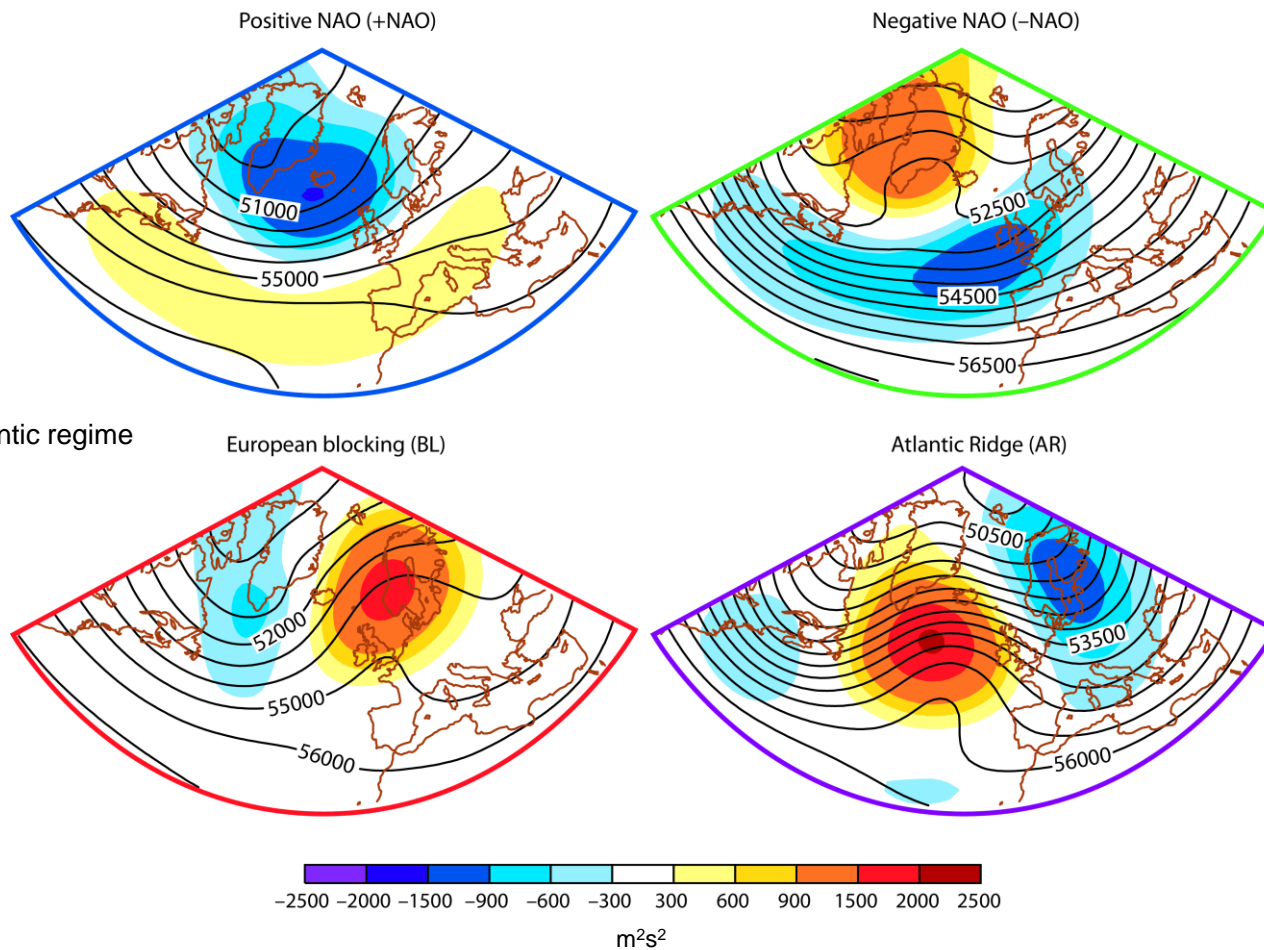

Danube, Feb 2012

- Heat/cold waves have a strong societal impact. The prediction of such events (onset maintenance and decay) a few weeks in advance would be very valuable.
- Vitart (2005) showed that the ECMWF ensemble had some skill in predicting the maintenance of the heat wave during the 2003 summer, but that the predictions of the onset and decay were less successful.
- Strong and persistent large scale high pressure systems are often associated with dry-spells, and with heat-waves in summer and cold-spells in winter. Accurate forecasts of transition to anti-cyclonic flow regimes are therefore crucial for heat/cold wave predictions.
- Here we explore the ability of the sub-seasonal forecast systems to predict the winter large-scale circulation patterns that are generally associated with cold spells over Europe.

Regimes based on clustering of daily anomalies for 29 cold seasons (1980-2008)

500 hPa geopotential

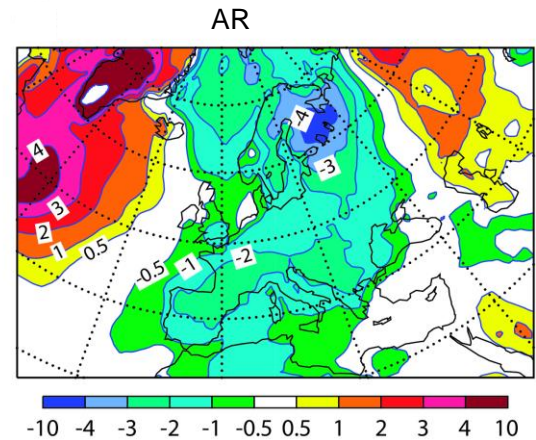

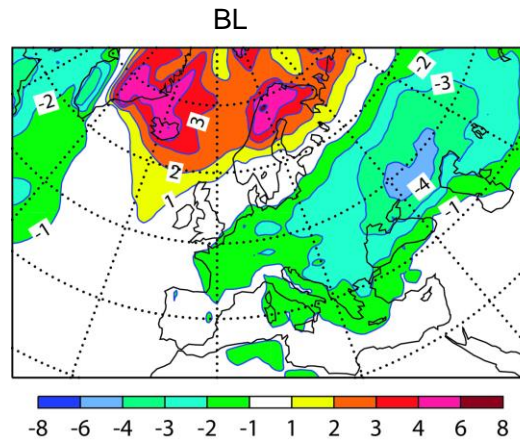

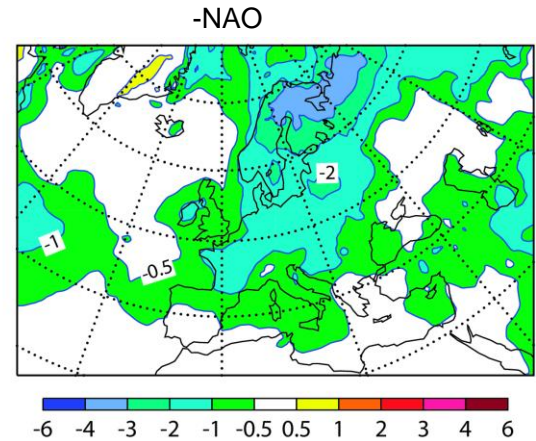

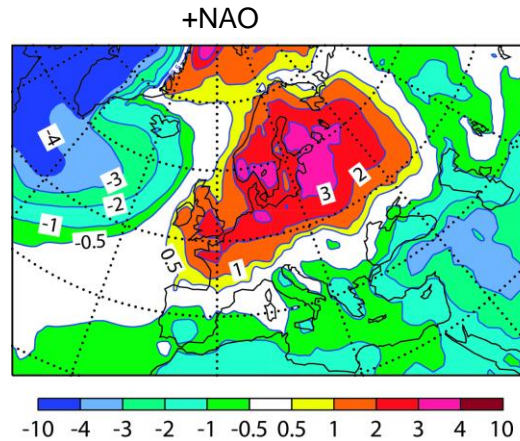

- Obtain well-known Euro-Atlantic regime patterns

'k means' clustering applied to EOF pre-filtered data (retaining 80% of variance)

2m temperature anomalies for persistent regime episodes (> 5days) in winter

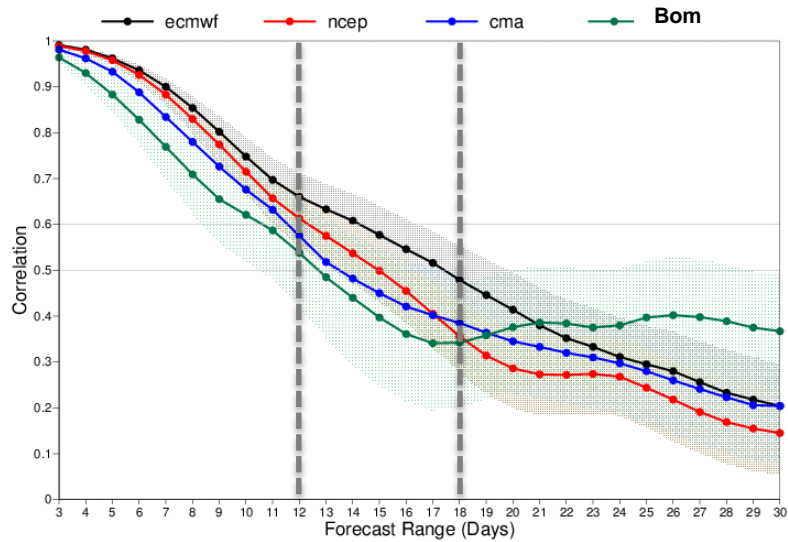

- Europe cold for 3 regimes
- BL and –NAO higher frequency of persistent events

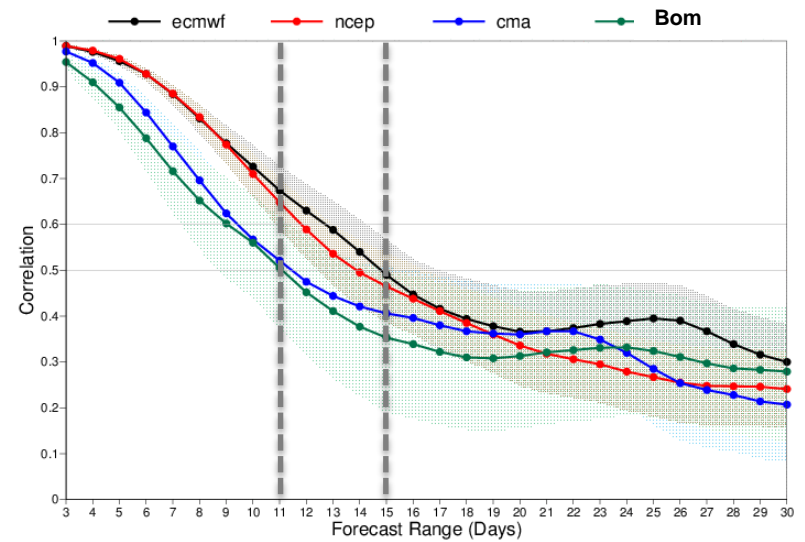

Based on re-forecast data (20 years)

Predicting skill associated with the Euro-Atlantic Regimes:

NAO +

NAO -

Blocking

Atlantic Ridge

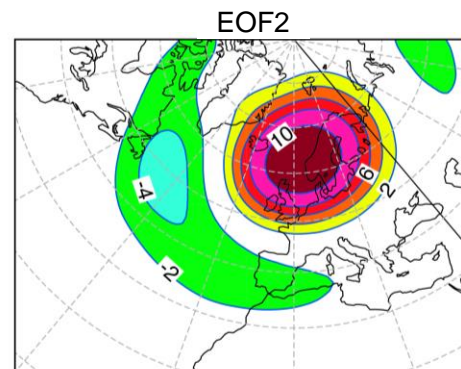

S2S reforecasts data used for the skill assessment:

model	Bom	Cma	Ecmwf	Ncep
Rfc. lenght	0-60 days	0-60days	0-46 days	0-44 days
Resol.	T47L17	T106L40	T639/319 L91	T126L64
Rfc. size	33	4	11	4
Rfc. period	1981-2013	1994-2014	1994-2014	1999-2010
Rfc. Freq.	6/months	daily	2/weekly	daily

In order to increase the Cma and Ncep ensemble size, we have combined 3 ensemble forecasts (initiated on consecutive days) into a single 12-member ensemble. (We define the initial date to be that of the central sub-ensemble; this has little effect on results at extended leadtimes).

Trajectories in phase space (c.f. MJO propagation)

- \pm EOF1 and +EOF2 represent quite well \pm NAO and BL
- Trajectories in phase space summarise regime evolution
- Unlike MJO, no preferred direction

BL: record-breaking cold temperatures over Europe

+NAO: exceptional storminess, but mild temperatures over Europe

Based on 5-day running means

Ensemble evolution in phase space

- Transition to blocking well-predicted 4 days ahead
- Nice way to summarise ENS in two dimensions
- Future: What processes involved in transition-to and maintenance-off blocking? Tropical forcing?

Initial date: 22 September 2015 UTC

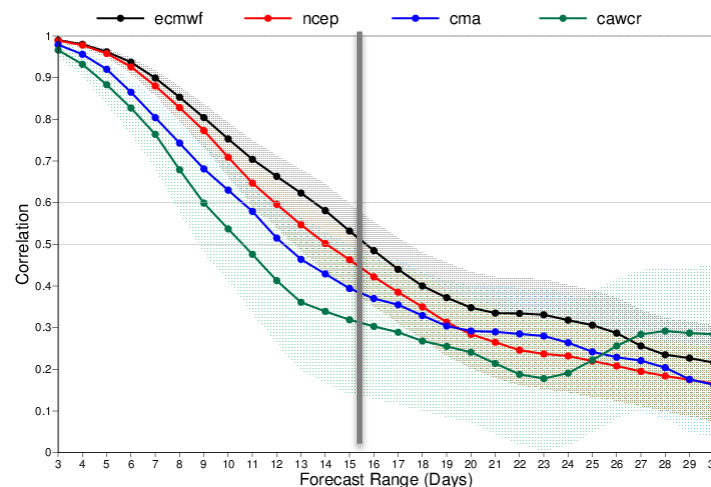

Regime transition-frequencies and predictability (c.f. MJO predictability)

Frequencies of transitions between persistent regimes (>5 days)

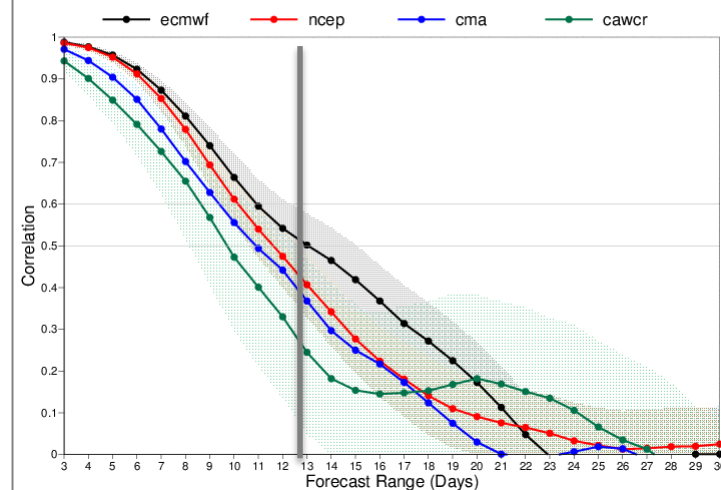

- Transition frequencies good. Slight over-preference for BL → +NAO
- ECMWF has 1-2 days better skill than NCEP
- PC1 is ~2 days better than PC2 (due to high persistence of -NAO?)

westerly - PC1 correlation

Sc. Blocking - PC2 correlation

5-day running mean applied prior to correlation calculation

S2S Z500 anomalies: days 12-18 - verifying 29-06 to 05-07 2015

S2S 2mt anomalies: days 12-18 - verifying 29-06 to 05-07 2015

Summary and discussion:

Preliminary results from the analysis on the cold events:

- S2S re-forecast dataset
- Assessing the predictive skill of the weather regimes associated with high impact temperature.
- Exploring a possible tool to characterize regime transitions

Monitoring the S2S forecasts – a small selection of basics products have been constructed.

Looking at the most recent heat wave over Europe (July 2015):

- importance of representing the transient waves
- In June the surface was very dry, a realistic surface initialization enhanced the extent of the temperature anomalies.

Observed anomaly: Mon 20150629- Sun 20150705

FC 20150625: Day 5-11

FC 20150618: Day 12-18

FC 20150611: Day 19-25

FC 20150604: Day 26-32
